Introduction

The bike rental business is growing rapidly for the last few years in major cities across the globe. Below are several important points about this business:

- o It reduces the traffic problem which is prevalent in almost all the cities.
- o People with no personal transport can opt for the service for their movement.
- o It may also help in mitigating pollution since most of the vehicles used in this business are electric or will be replaced by electric.
- o This business involves large investments both in physical and non-physical infrastructure.

Objective: It is essential to develop systems that help in flawless operations in this business. One of the sections of the entire system is to know the approx. number of bikes that must be available. On the basis of the given dataset that contains previous records, we can develop a machine learning (ML) model to predict the number of required bikes at a given point of time for better customer experience and overall revenue or profitability.

Methodology: Machine Learning (ML) Linear Regression (Supervised ML Model)

Database Summary:

- o It is a public bike rent dataset of Seoul the capital city of South Korea.
- It has 8740 rows and 14 columns
- o The values in the dataset are of 3 categories i.e. Numerical, Categorical and Datetime.
- The dataset has broadly four pieces of information in different columns, these are: column about the number of bikes, columns having information about date, time, month etc, columns about days of operations and columns about the climate or weather.

Data Preparation

The database has the following features:

- Date Day/Month/Year
- Rented Bike Count Number of Bikes rented every hour
- Hour Hour of the day
- Temperature-Temperature in Celsius
- o Humidity %
- Windspeed m/s
- Visibility 10m
- Dew point temperature Celsius
- Solar radiation MJ/m2
- o Rainfall mm
- o Snowfall cm
- Seasons Winter, Spring, Summer, Autumn
- Holiday Holiday/No holiday
- Functional Day NoFunc(Non Functional Hours), Fun(Functional hours)

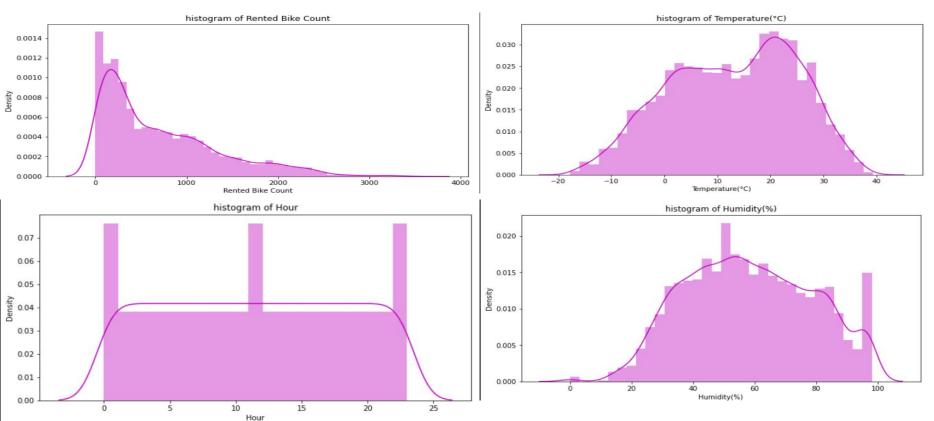

Overview of Dataset

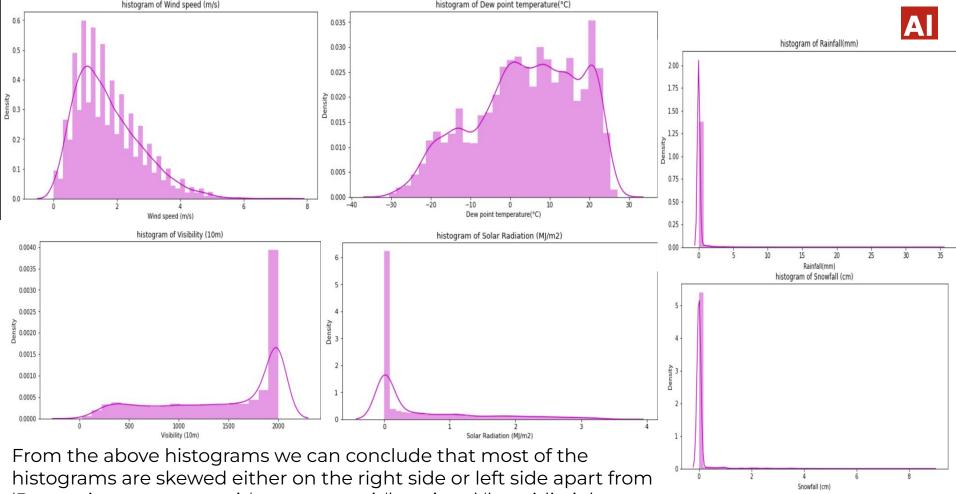

- It has no 'NaN' or 'Null' values
- o It has no duplicate values
- o It contains the hourly record of bike rentals from December 1, 2017, to November 30, 2018, i.e. of an entire year.
- 'Rented Bike Count' is a dependent feature.
- o Day (number and name), Month (number and name) and Year were extracted from the 'Date' column.
- After creating new features from the 'Date' feature the entire dataset contains only 'numerical' and 'categorical' datatype.
- 'wind_speed', 'solar_radition', 'rainfall', 'snowfall' and 'Rented Bike Count' have outliers.

Plots of the Distribution of Numerical Features

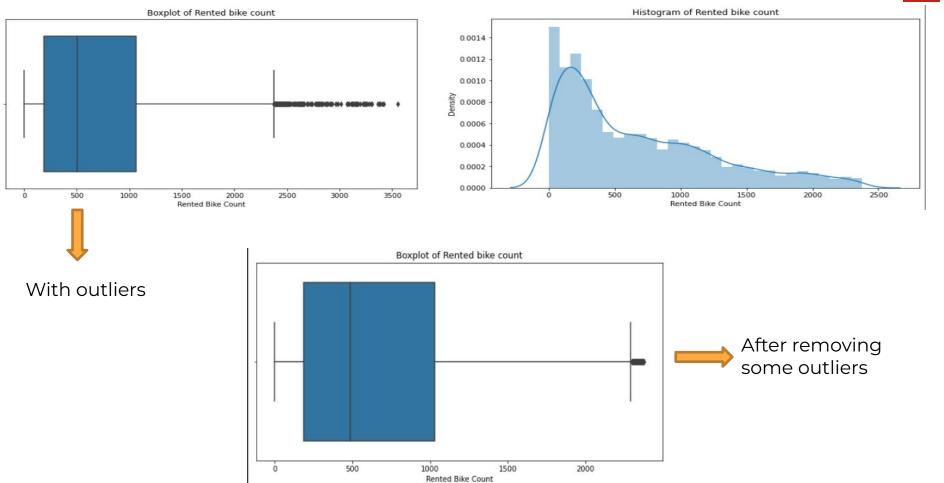

histogram of Dew point temperature(°C)

'Dew point temperature', 'temperature', 'hour' and 'humidity' these are normally distributed.

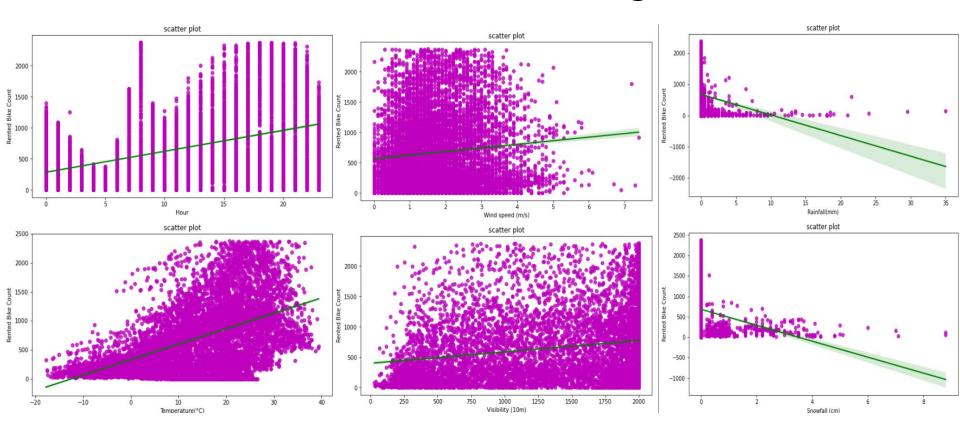

Outlier – Dependent Feature

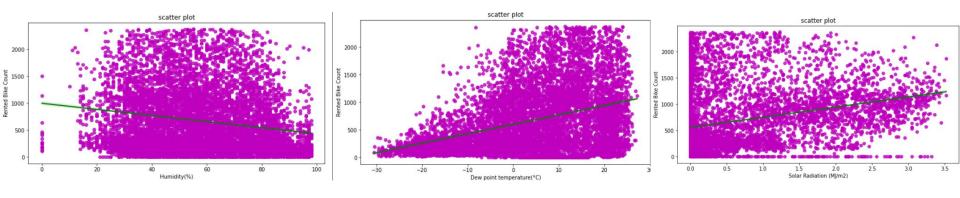

Scatter Plot with Linear Regression

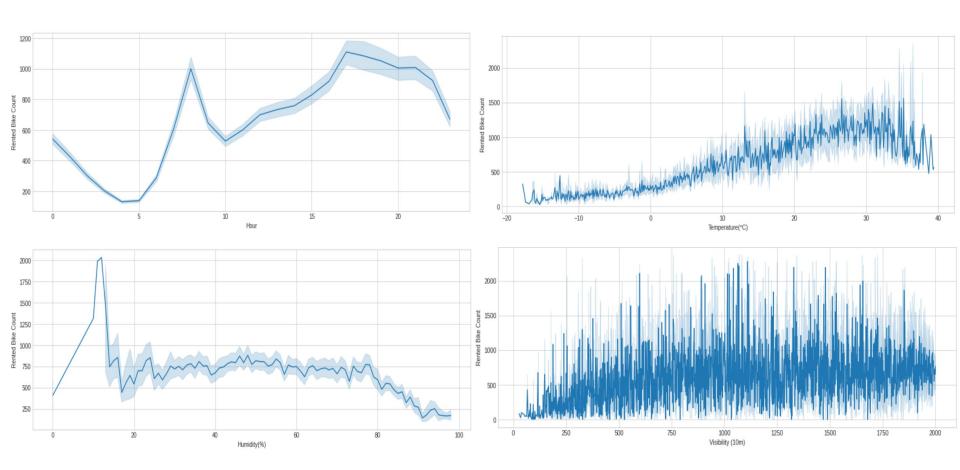

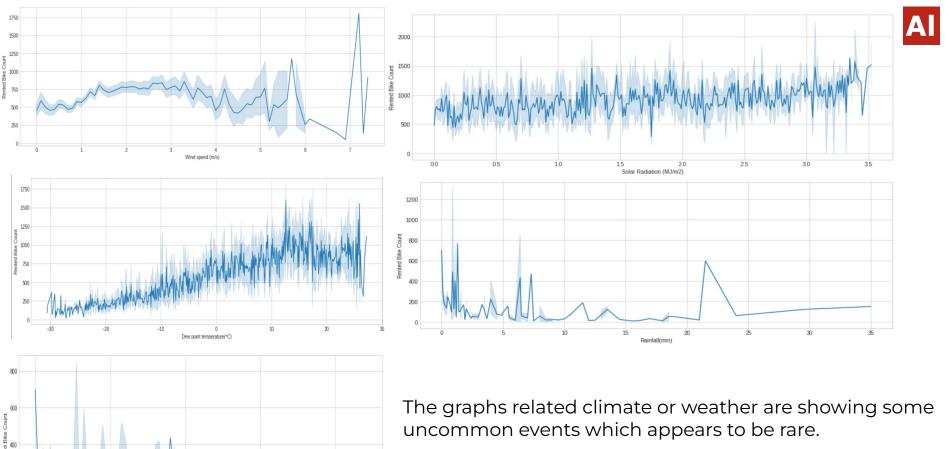

- i. Hour, Wind speed, Temperature, Visibility, Dew Point Temperature and Solar Radiation have positive co-relation with the number of Rented Bikes.
- ii. Rainfall, Snowfall and Humidity have negative co-relation with the number of Rented Bikes.

Graph to show the distribution of numerical features

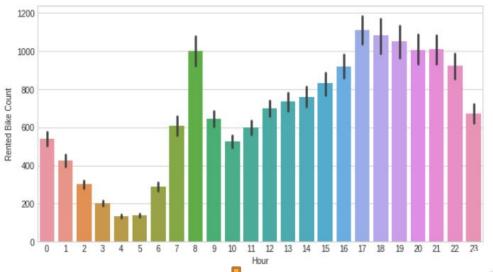

The graphs related councommon events v

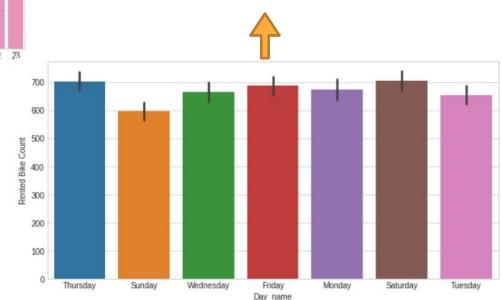

Rented Bikes on Different Occasions

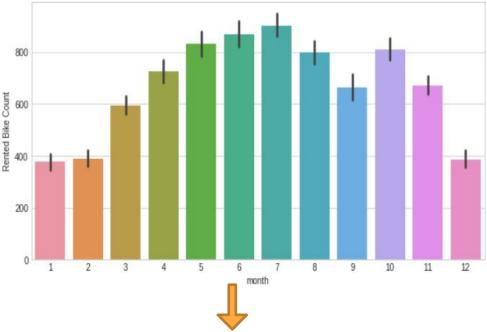

The average number of rented bikes on different days not showing any significant variation, it is nearly the same except for the Sunday.

- 8 A.M. has the highest number of rented bikes in morning while later at 5 P.M. it is highest (overall).
- We can say that working hours has higher traffic.

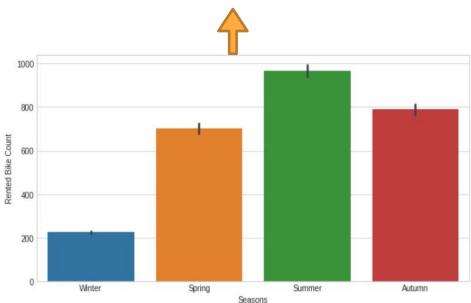

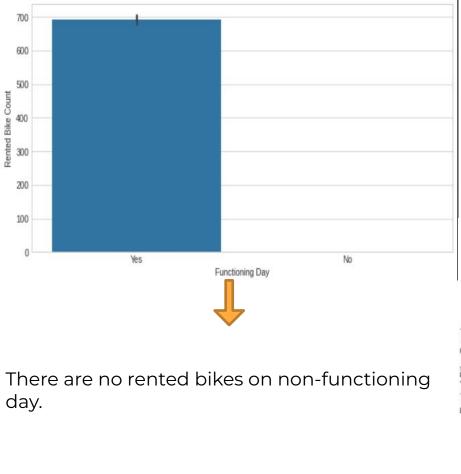

July (7) month has the highest while January (1) has lowest number of rented bike record.

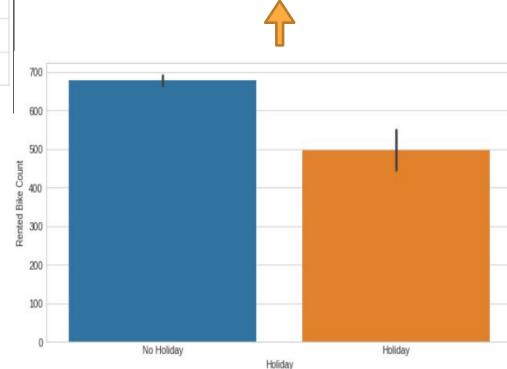

- Summer has the highest while winter has the lowest number rented bikes.
- The weather or climatic condition is directly affecting the overall number of rented bikes.

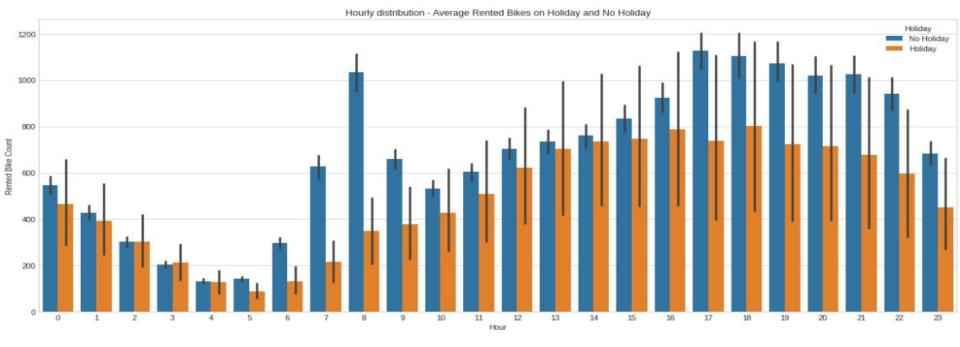

Plot to show the hourly average of rented bikes on Holiday and No Holiday

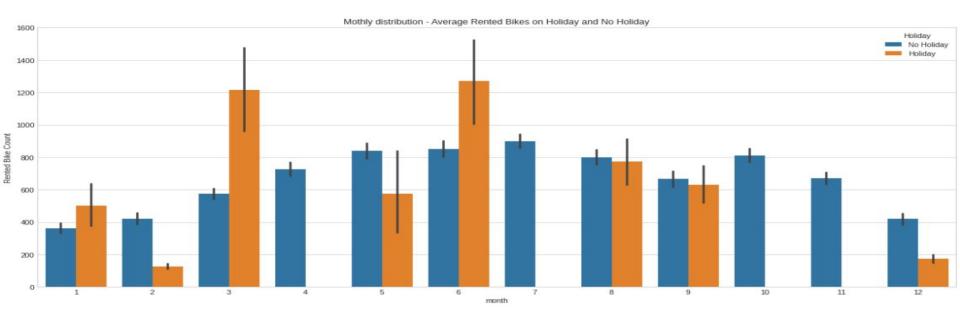

- o Overall the day without holiday has highest rented bikes across the day.
- o Only at 3 A.M. has the number of rented bikes on holiday are slightly higher as compare to the no-holiday.

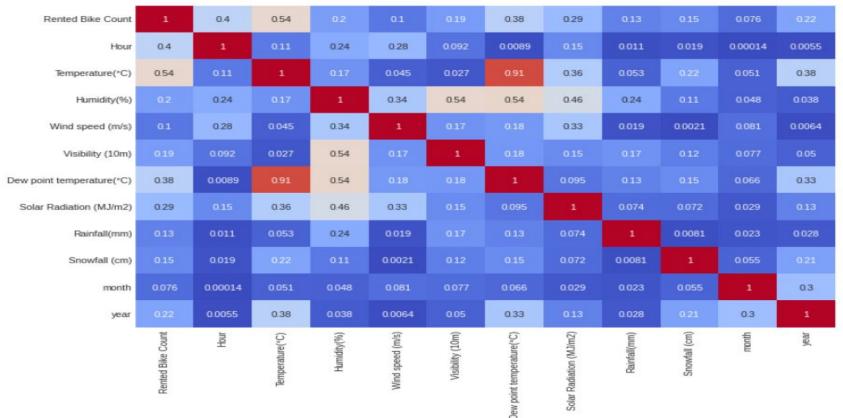

Plot to show the Monthly distribution of average rented bikes on Holiday and No Holiday

- The month of January (1), March (3), June (6) have recorded more bike rents on holiday than no-holiday.
- o The month of February (2), May (5), August (8), September (9) and December (12) have recorded more bike rents on no-holiday than the holiday.
- The month of April (4), July (7), October (10), November (11) only have records of no-holiday.

Heat Map

'Temperature' and 'Dew point temperature' are highly correlated so we can remove the 'Dew point temperature'.

Challenges

- o The Dataset is large.
- The project requires some domain knowledge.
- Some features are interconnected so the feature selection was challenging.
- Large graphical representation was required.
- Instances of rare events esp. related to climate or weather were mentioned in the dataset.
- Different algorithms were giving different performance scores and the variation was large.
- The number of features was affecting the overall model performance.

Conclusion

- o There are several features that are impacting the overall bike rental trend, these features are 'Hour', 'Season', 'Holiday' or 'No Holiday', and those covering climate esp. 'rainfall' and 'snowfall'.
- There are no operations of agency on non-functioning days so no bikes were rented during those days.
- o Among different seasons 'Summer' has the highest while 'winter' has the lowest number of bike rentals.
- The outliers that the graphs of 'wind speed', 'solar radiation', 'rainfall' and 'snowfall' show are not the outliers.
- o Snowfall and rain do affect the bike rentals as the number reduces during such and days with clear weather have higher number rented bikes.
- Non-Holidays or working days have a higher number of rented bikes during 7-9
 AM and later 5-10 PM. While on holidays there is not any specific peak time.
- o Out the all the models that are used Random Forest has the highest R2 Score i.e. Train-0.976 (approx.), Test-0.848(approx.).

Thank You
